Contributors: This coho forecast was made possible through field data collection and local sources and the participation of numerous WDFW, tribal, and local sources and the participation of numerous WDFW, tribal, and local WDFW employees, listed in alphabetical order, provided field data collection (Snow Creek), Josh Holowatz (Cedar Creek), Todd Hills (Abernathy, and Germany creeks), Clayton Kinsel (Skagit River and Washington), Matt Klungle (Nisqually River), Jamie Lampert (Falls), Pete Topping (Green River, Deschutes River), Devin West (Chehalis River). Smolt data obtained from tribal and PUD biologists. Freshwater and marine environmental indicators are cited in Volkhardt, Dan Rawding, and Thomas Buehrens have contributed to this forecast.

Introduction

Run size forecasts for wild coho stocks are an important part of Washington State salmon fisheries. Accurate forecasts are needed to ensure adequate spawning escapements, realize harvest benefits, and maintain wild coho stocks.

Wild coho run sizes (adult ocean recruits) have been predicted in Washington's coho producing systems. Methods that rely on escapement and resulting run sizes are problematic due to the difficulty allocating catch in mixed stock fisheries. In addition, escapement has no predictive value because watersheds become fully stocked (Bradford et al. 2000). Furthermore, different variables in the freshwater (Lawson et al. 2004) and marine environments (Nickelson 1986; Bradford et al. 2003) influence coho survival and recruitment to the next life stage. Run size forecasts can be improved by partitioning recruitment into freshwater survival. In this forecast, wild coho run sizes (adult ocean recruits) and marine survival and are expressed in a matrix that combines freshwater and marine survival. This is similar to that used to predict hatchery returns where the survival (released) is known.

Freshwater production, or smolt abundance, is measured as the number of fish released at the conclusion of the freshwater life stage. The

- Successful predictions of marine survival in wild coho populations on the WA coast (Bingham Creek)
- Are they useful for Lower Columbia natural coho?

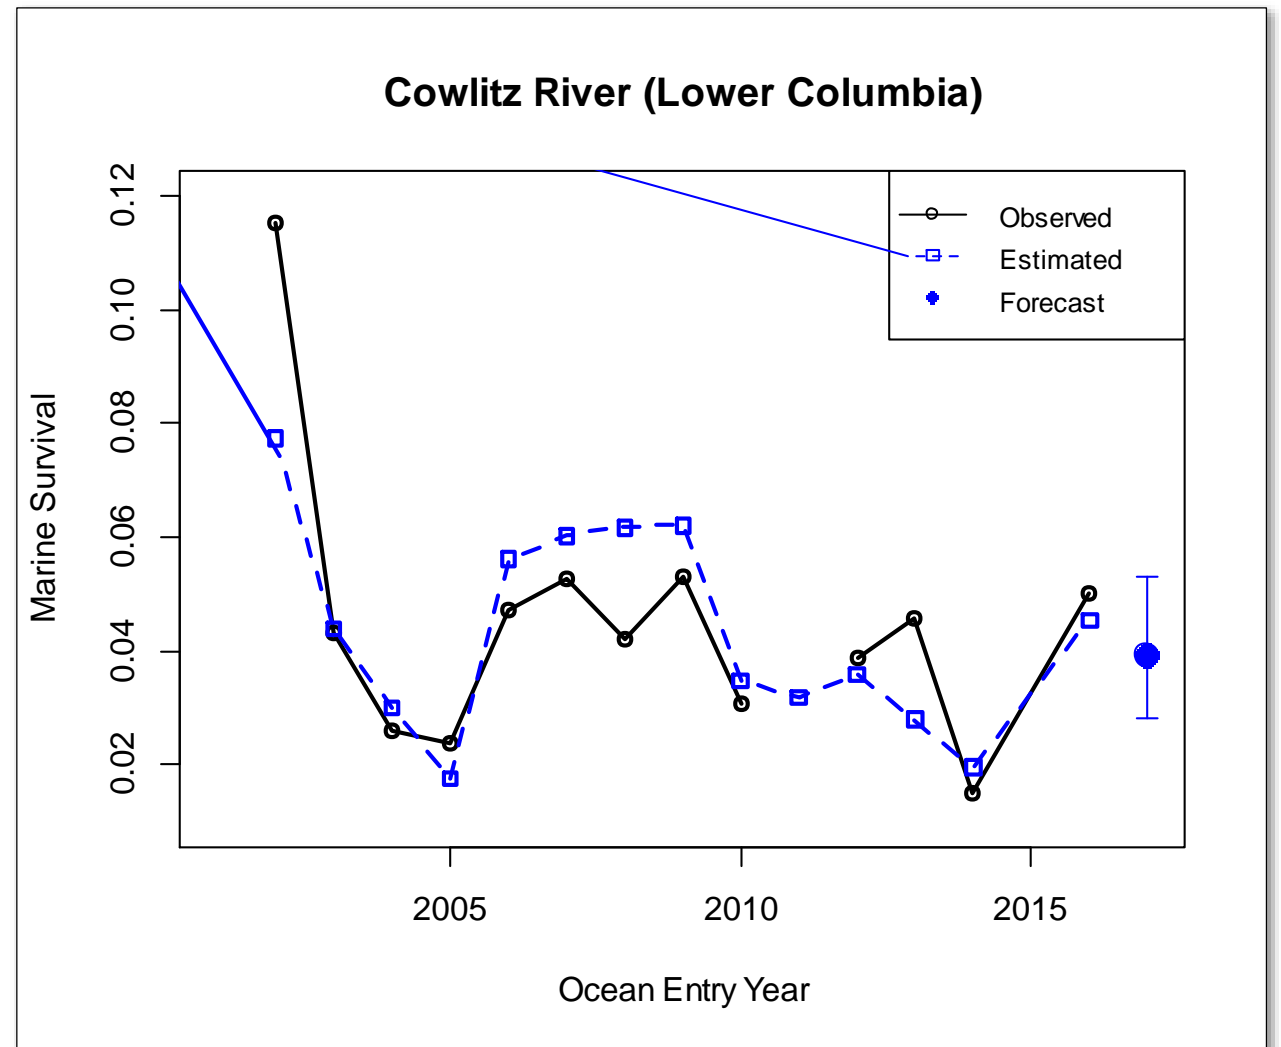

Lower Columbia River Natural Coho – Marine Survival

- Ocean, regional, local scales
- Examine individual regressions
- 9 of 24 variables correlated with marine survival

Lower Columbia River Natural Coho – Marine Survival

- Multiple regression model
 - Upwelling length
 - Sea surface temperature (NH05)
- Leave-one-out validation
 - MPE = -3.5%
 - MAPE = 21.2%
- Caveats
 - Short time series
 - 2001, 2015 OEY

Lower Columbia River Natural Coho Forecasts

- Forecasts of natural coho (distinct from hatchery forecasts) important for Columbia River fishery management
- Sibling regression approach has uncertainties for natural populations
- Forecast approach incorporates smolt estimates, marine survival predictions
- Ecosystem indicators of marine survival
 - Caveat: short time series
 - Physical indicators more informative than biological indicators
 - OR coastal natural coho (Logerwell et al. 2003)
 - Col R hatchery coho (Ryding and Skalski 1999)
